

Resume Website Enhancement Using CSS

Name: Priyanshi Saini | **Roll No.:** 25120731 | **Course:** BBA DBE — Batch 2

Module: Web Development — Mid-Term Project | **Date:** 8 September 2026

1. Project Overview

This project takes the personal resume website built during the HTML module and rebuilds its presentation layer using CSS. The original page was structurally correct but visually plain: stacked sections, default spacing and a single gradient. The objective was to apply the CSS concepts covered in this module — fonts, colour, selectors, the box model, display and positioning — to produce a clean, professional and fully responsive single-page resume, and to redeploy it to the same GitHub repository via GitHub Pages.

2. Improvements Made

- **Added a sticky navigation bar using flexbox** — `display: flex` with `justify-content: space-between` aligns the logo, links and call-to-action button in one row, and `position: sticky; top: 0` keeps it visible while scrolling.
- **Used Google Fonts for a clear type hierarchy** — *Fraunces* (serif) for headings paired with *Inter* (sans-serif) for body text, giving the page a professional, readable feel instead of one single typeface.
- **Defined a consistent colour palette with CSS variables** — navy, blue accent and off-white neutrals declared once in `:root` as custom properties, so every colour in the site is controlled from a single block of code.
- **Built a two-column hero header** using flexbox, with an absolutely positioned radial glow (`::before`) behind the content and a translucent profile card showing name, roll number and course.
- **Organised styling with element, class and ID selectors** — element selectors for base typography, reusable classes such as `.card`, `.btn` and `.skill` for repeated components, and ID selectors (`#navbar`, `#hero`, `#about`) for unique page regions.
- **Converted every section into a card layout** with white surfaces, soft borders, rounded corners and shadows; a negative top margin on `<main>` lifts the first card over the hero for an overlapping effect, controlled with `position: relative` and `z-index`.
- **Used CSS Grid for the Skills and Projects sections** — `grid-template-columns: repeat(auto-fit, minmax(230px, 1fr))` lets the cards reflow automatically from three columns to one as the screen narrows.
- **Created an education timeline with pseudo-elements** — a left border acts as the timeline and `::before` circles positioned absolutely mark each entry.
- **Added hover effects and transitions** — animated underlines on nav links, lift-on-hover on cards and projects, colour fills on buttons and skill tags, all driven by a shared transition variable.
- **Improved alignment, spacing and text formatting** — a shared `--max-width` container, consistent padding and gap values, `clamp()` for fluid heading sizes, uppercase letter-spaced section labels and a comfortable 1.7 line height.
- **Made the layout responsive** with media queries at 900px and 640px that stack the hero, resize the navigation and reduce padding on small screens.
- **Expanded the content and refined the JavaScript** — added Education, an itemised Skills section with proficiency bars, three project cards and a structured contact block; the old `alert()` was replaced with an inline animated greeting message and scroll-based highlighting of the active navigation link.

3. Technologies Used

- **HTML5** — semantic page structure
- **CSS3** — flexbox, grid, variables, transitions
- **JavaScript** — small interactive touches
- **Git, GitHub & GitHub Pages** — version control and hosting

4. Preview of the Updated Website

Redesigned resume website — sticky navigation bar, hero header and card-based sections.

5. Learning Outcome

Working through this project made it clear how much of a website's usability comes from CSS rather than from content alone. Rebuilding the same information with a proper type scale, a limited colour palette and consistent spacing made the page far easier to scan. Flexbox and grid were the biggest takeaways — being able to describe a layout in terms of direction, alignment and gaps is much more reliable than adjusting margins by trial and error. Using CSS variables and reusable classes also showed why organising selectors well matters: changing one value in `:root` restyles the whole site, which is impossible with scattered, repeated rules.

6. Conclusion

The updated website is cleaner, better structured and responsive across desktop and mobile screens, while keeping the original content intact. The project strengthened my confidence in writing organised CSS and in using Git and GitHub Pages to publish and update a live site.
